

cies grow at elevations of 5000 feet in the edge of the tropics where ice forms more or less regularly.

Mr. H. Godfrey Mundy, government agriculturist and botanist of Salisbury, Rhodesia, called recently. Among the plants discussed were the mahobohobo, *Uapaca sansibarica*, a euphorbiaceous fruit described as a "wild loquat" with a banana flavor, and the elephant grass, *Pennisetum purpureum*, a heavily stooling perennial, always propagated by cuttings or root division, and considered by him as preferable to teosinte. Mr. Mundy reports that the Rhodes grass which is native of Rhodesia does not there make a satisfactory growth and is not used as a forage grass.
